

# Relation Extraction

Justin T. Chiu

July 31, 2019

## Abstract

Recent relation extraction systems predict the relationship between an entity and value given the positions of their mentions in the text. This requires words to be annotated as mentions. The cost of obtaining human annotations for each word scales linearly with the size of the text. Automatic annotation methods allow the annotation process to scale sublinearly in human effort, but may introduce noise due to incorrect annotations. In order to train a probabilistic information extraction model without mention annotations, we specify a model that, identifies important words and uses them to explain a triple from a knowledge base.

## 1 Problem Statement

Relation extraction aims to extract facts from a passage of text. Extraction systems convert facts expressed in natural language into a form amenable to computation. Facts consist of three components: Entities, relation types, and values. The challenge is to not only extract facts from text, but also justify the extractions by determining where those facts are mentioned. In order to justify the extraction, we locate the fact’s *trigger*, which clearly expresses its occurrence. We make the assumption that a fact’s trigger is its value mention.

The problem description is as follows: Given a textual summary  $x = x_1, \dots, x_I$  of length  $I$ , we model the aligned knowledge base (KB)  $\{(k_j, v_j)\}_{j=1}^J$  consisting of keys  $k = \{(e_j, t_j)\}_{j=1}^J$ , obtained by combining the entity  $e_j$  and type  $t_j$  in a fact, and values  $v = \{v_j\}_{j=1}^J$ ,  $v_j \in \mathcal{V}$ . The KB  $(k, v)$  contains  $J$  facts, or  $(k_j, v_j)$  pairs. Our goal is to locate and extract facts from  $x$  by modeling the values  $v$  given the text  $x$  and the keys  $k$ .

Modeling only the KB  $(k, v)$  given the text  $x$  is not sufficient, as our goal is to locate fact mentions. We assume the KB contains many more facts than those mentioned in the text. This fits many scenarios in real world applications: We may have many entity and type key pairs in our KB, but a summary may discuss only a small, salient subset of players and statistics. We therefore propose a model that first identifies words as value mentions, aligns those mentions to an entity and relation type in order to obtain a fact, and then aggregates word-level decisions into a sequence-level decision to resolve conflicts.

Consider the following example: Let our KB consist of the data table and values,

$$D = \left\{ \begin{array}{l} k_1 = (e_1 = \text{John Doe}, t_1 = \text{POINTS}), \\ k_2 = (e_2 = \text{John Doe}, t_2 = \text{REBOUNDS}), \\ k_3 = (e_3 = \text{John Doe}, t_3 = \text{FIRST\_NAME}), \\ k_4 = (e_4 = \text{John Doe}, t_4 = \text{LAST\_NAME}), \\ \vdots \end{array} \right\}, v = \left\{ \begin{array}{l} v_1 = 8, \\ v_2 = 12, \\ v_3 = \text{'John'}, \\ v_4 = \text{'Doe'}, \\ \vdots \end{array} \right\}$$

aligned to the summary  $x = \text{'John Doe scored eight points'}$ . As an example extraction, we identify the value mention **'eight'** as the trigger for the fact mention  $(k_1, v_1)$ .

## 1.1 Model

In order to perform extraction with justification we introduce the following latent variables:

- $m = m_1, \dots, m_I$  where each  $m_i \in \{0, 1\}$  indicates whether word  $x_i$  is part of a value mention. We aim to identify at least one word in a multiword mention.
- $a = a_1, \dots, a_I$  where each  $a_i \in \{1, \dots, J\}$  indicates that word  $x_i$  mentions the fact with key  $k_{a_i}$ .
- $z = z_1, \dots, z_I$  where each  $z_i \in \mathcal{V}$  translates the value mention containing word  $x_i$  into the canonical representation of the value as determined by the schema of the KB. For example, the KB may only store numbers in numerical form, as opposed to alphabetical.

Our model specifies the joint distribution over the values and latent variables given the text and keys:

$$\begin{aligned} p(v, z, a, m \mid x, k) &= p(v \mid z, a, m, x, k) p(z, a, m \mid x, k) \\ &= \underbrace{\left( \prod_{j=1}^J p(v_j \mid z, a, m, x, k) \right)}_{\text{Aggregation}} \underbrace{\left( \prod_{i=1}^I \underbrace{p(z_i \mid m_i, x)}_{\text{Translation}} \underbrace{p(a_i \mid m_i, x, k)}_{\text{Alignment}} \underbrace{p(m_i \mid x)}_{\text{Identification}} \right)}_{\text{Extraction}} \end{aligned} \quad (1)$$

The extraction model has three components. The model must identify whether word  $x_i$  is a mention using the *identification* model  $p(m_i \mid x)$ , align word  $x_i$  to a key  $k_{a_i}$  via the *alignment* model  $p(a_i \mid m_i, x, k)$ , and translate the word  $x_i$  into a value  $z_i$  with the *translation* model  $p(z_i \mid m_i, x)$ .

This model assumes that each word  $x_i$  can explain at most one fact in the KB. Additionally, we make the simplifying assumption that a value mention's translation is unambiguous. This allows us to make all choices independently for each word given the text  $x$  and keys  $k$ .

It is possible for there to be conflicts in the word-level extraction model if two words are mentions with the same alignment but different values. The aggregation model  $p(v_j \mid z, a, m, x, k)$  is necessary to resolve these conflicts, and uses the per-word extractions to predict the values of the KB.

We give the parameterizations of all conditional distributions in the following section.

Figure 1: Our model predicts word-level values and alignments then aggregates those choices over all indices  $i$  to make a single decision for each value. Each word has the following latent variables: the mention  $m_i \in \{0, 1\}$  indicates whether word  $x_i$  is a value mention, the alignment  $a_i$  gives the cell  $k_{a_i}$  that  $x_i$  aligns to, and the value  $z_i$  gives the canonical value that  $x_i$  translates to.

## 1.2 Parameterization

We parameterize the conditional distributions for mention identification, alignment, translation, and aggregation below.

Let  $\mathbf{h}_i \in \mathbb{R}^d$  be a contextual embedding of the word  $x_i$ , and  $E$  an embedding function that maps keys  $k$  to vectors in  $\mathbb{R}^d$ .

1. Identification: We use the contextual embedding to predict whether a word  $x_i$  is part of a value mention.

$$p(m_i | x) \propto \exp(W_m \mathbf{h}_i)_{m_i}, W_m \in \mathbb{R}^{2 \times d} \quad (2)$$

2. Alignment: We use a bilinear function of the cell embeddings and contextual embeddings to parameterize the alignment distribution.

$$p(a_i | m_i = 1, x, k) \propto \exp(E(k_{a_i})^T W_a \mathbf{h}_i) \quad (3)$$

with  $W_a \in \mathbb{R}^{d \times d}$ .

3. Translation: We use the contextual embedding to translate a word into a value.

$$p(z_i | m_i = 1, x) \propto \exp(W_z \mathbf{h}_i)_{z_i}, W_z \in \mathbb{R}^{|\mathcal{V}| \times d} \quad (4)$$

4. Aggregation: We choose the value associated with a particular key in the KB by first using the translated values of any mentions aligned to the corresponding key. If no mention is aligned to the key, we instead ignore the text and choose the value given only the key.

Formally, the conditional distribution is given by

$$p(v_j \mid z, a, m, k) \propto \begin{cases} \prod \exp(\psi(v_j, z_i, a_i, m_i, k)), & \exists i, m_i = 1 \wedge a_i = j \\ \exp(E(v_j)^T W_v [E(k_j)]), & \text{otherwise} \end{cases} \quad (5)$$

$$\psi(v_j, z_i, a_i, m_i, k) = \mathbf{1}(v_j = z_i, a_i = j, m_i = 1) \quad (6)$$

## 2 Training and Inference

To train a latent variable model, we must marginalize over the unobserved RVs and maximize the likelihood of the observed. Although the latent variables  $z, a, m$  are important, as they indicate where and what facts are contained in the text, they are not observed and must be marginalized over. Therefore we would ideally optimize the following objective

$$\log p(v \mid x, k) = \log \sum_{z, a, m} p(v, z, a, m \mid x, k) \quad (7)$$

However, maximizing  $\log p(v \mid x, k)$  directly is very expensive for this model as the summation over variables  $z, a, m$  is intractable; in particular, the summation has computational complexity  $O((|\mathcal{V}| \cdot J \cdot 2)^I)$ .

We therefore resort to approximate inference, specifically amortized variational inference.

### 2.1 Inference Network

We introduce an inference network  $q(z, a, m \mid v, x, k)$  and optimize the following lower bound on the marginal likelihood with respect to the parameters of both  $p$  and  $q$ :

$$\log p(v \mid x) \geq \mathbb{E}_{q(z, a, m \mid v, x, k)} \left[ \log \frac{p(v, z, a, m \mid x, k)}{q(z, a, m \mid v, x, k)} \right] \quad (8)$$

We use the same contextual embedding  $\mathbf{h}_i \in \mathbb{R}^d$  of the word  $x_i$  from the extraction system, and we extend the embedding function  $E$  to embed not only keys but also values. We introduce the following attention weights over records in order to get a weighted representation of the KB for each index  $i$ :

$$\mathbf{g}_j = [E(k_j); E(v_j)] \quad (9)$$

$$\alpha_j \propto \exp(\mathbf{g}_{r_j}^T W_\alpha \mathbf{h}_i) \quad (10)$$

We propose to parameterize the inference network  $q(z, a, m \mid v, x, k)$  as follows:

1. Identification: To predict whether  $x_i$  is a mention, the inference network uses a weighted representation of the KB along with the contextual representation  $\mathbf{h}_i$

$$p(m_i \mid v, x) \propto \exp \left( V_m \text{MLP} \left( \left[ \sum_j \alpha_j \cdot \mathbf{g}_j; \mathbf{h}_i \right] \right) \right)_{m_i}, V_m \in \mathbb{R}^{2 \times d} \quad (11)$$

where MLP is a neural network.

2. Alignment: The alignment model  $q(a_i \mid v, x, k)$  uses the attention weights to parameterize the alignment  $p(a_i \mid x) = \alpha_{a_i}$ .
3. Translation: The translation model  $q(z_i \mid a_i, v, x) = \mathbf{1}(z_i = v_{a_i})$  conditions on the alignment  $a_i$  and ensures the chosen  $z$  is consistent with the alignment.

The joint distribution of  $z, a, m$  in the inference network is given by

$$\begin{aligned} p(z, a, m \mid v, x, k) &= p(z \mid a, v, x) p(a \mid v, x, k) p(m \mid v, x) \\ &= \prod_i p(z_i \mid a, v, x) p(a_i \mid v, x, k) p(m_i \mid v, x) \end{aligned} \quad (12)$$

We use the score function gradient estimator to perform gradient ascent on the objective in Equation 12 with respect to both  $p$  and  $q$ . We utilize a leave-one-out baseline for variance reduction.

One concern is that the model may learn to never rely on the text for extraction, setting  $m_i = 0$  for every word  $x_i$ . We can avoid this by pretraining  $p(z_i \mid x)$  to ensure that for words  $x_i$  where there exists a  $z_i \in \mathcal{V}$  such that  $x_i$  and  $z_i$  are a lexical match we assign high probability to the transliteration  $p(z_i = x_i \mid x)$ .

### 3 Evaluation

We are interested in evaluating whether the model can discover and locate the subset of facts in a KB that are expressed in the text without observing the values of the KB. We compare the extractions of our model with a ground truth set of facts extracted by a human annotator, reporting the micro-averaged precision, recall, and F1 score. The ground truth facts consist of entities, types, values, as well as the location of their value mention in text.

We perform extraction by finding

$$\arg \max_{z_i, a_i, m_i} p(z_i \mid x), p(a_i \mid x, k), p(m_i \mid x)$$

for each word  $x_i$ . We obtain the fact  $(e_j, t_j, v_j)$  at position  $i$  if  $m_i^* = 1$ ,  $a_i^* = j$  and  $z_i^* = v_j$ . The extraction is considered correct if the ground truth contains a fact with the same entity, type, value, and location.
